

PROGRAMMING IN HASKELL

Equational Reasoning and Induction

Equational Reasoning

Functional Programming

- What is functional programming? Some possible answers:
 - Programming with first-class functions
 - `map (\x -> x + 1) [1,2,3]` $\sim > [2,3,4]$
 - Programming with mathematical functions
 - No side-effects (no global mutable state, no IO)
 - Calling a function with the same arguments, always returns the same output (not true in most languages!)

Reasoning about Purely Functional Programs

- When programs behave as mathematical functions, standard mathematical techniques can be used to reason about such programs.
- Such techniques include:
 - **Equational reasoning**: Interpret programs as equations; substitute equals by equals
 - **Structural induction**: The use of recursion means that reasoning techniques such as induction are useful.

Equational reasoning in mathematics

- Whenever we have a system of mathematical equations, we can use equational reasoning to reason about such equations. For example:

$$x = y + z$$

$$y = 3z$$

$$z = 5$$

- Suppose we want to find the value of x

Equational reasoning in mathematics

- Using annotated steps we proceed as follows

$$x = y + z$$

$$\equiv \{\text{definition of } y\}$$

$$x = 3z + z$$

$$\equiv \{\text{simplification}\}$$

$$x = 4z$$

$$\equiv \{\text{definition of } z\}$$

$$x = 4 * 5$$

$$\equiv \{\text{simplification}\}$$

$$x = 20$$

Proving that Option is a Monad

- Using equational reasoning and structural induction we can show that the Option instance

instance Monad Option where

$\text{return } x = \text{Some } x$

$\text{None} >>= f = \text{None}$

$(\text{Some } x) >>= f = f\ x$

satisfies the monad laws:

$\text{return } a >>= k = k\ a$

$m >>= \text{return} = m$

$m >>= (\lambda x \rightarrow k\ x >>= h) = (m >>= k) >>= h$

Proving that Option is a Monad

- First law:

return a >>= k
≡ {definition of return}
Some a >>= k
≡ {definition of >>=} k a

Proving that Option is a Monad

- Second law:

$m \gg= \text{return}$

$\equiv \{\text{by induction on } m\}$

1) Case m is `None`

$\text{None} \gg= \text{return}$

$\equiv \{\text{definition of } \gg=\}$

`None`

2) Case m is `Some a`

$\text{Some } a \gg= \text{return}$

$\equiv \{\text{definition of } \gg=\}$

$\text{return } a$

$\equiv \{\text{definition of return}\}$

`Some a`

Proving that Option is a Monad

- Third law:

$m >>= (\backslash x \rightarrow k\ x >>= h)$

$\equiv \{\text{case analysis (or induction) on } m\}$

1) Case m of `None`

$\text{None} >>= (\backslash x \rightarrow k\ x >>= h)$

$\equiv \{\text{definition of } >>=\}$

`None`

$\equiv \{\text{definition of } >>=\}$

`None` $>>= h$

$\equiv \{\text{definition of } >>=\}$

$(\text{None} >>= k) >>= h$

Proving that Option is a Monad

- Third law:

$m >>= (\backslash x \rightarrow k\ x >>= h)$

$\equiv \{\text{case analysis (or induction) on } m\}$

2) Case m of $\text{Some } a$

$\text{Some } a >>= (\backslash x \rightarrow k\ x >>= h)$

$\equiv \{\text{definition of } >>=\}$

$(\backslash x \rightarrow k\ x >>= h)\ a$

$\equiv \{\text{simplification}\}$

$k\ a >>= h$

$\equiv \{\text{definition of } >>=\}$

$(\text{Some } a >>= k) >>= h$

Structural Induction

Induction in mathematics

Induction decomposes a proof into two parts:

- **Base case(s)**: Prove that the property holds for the base cases.
- **Inductive step(s)**: Prove that the property holds for the recursive cases.

Induction in mathematics

The simplest and most common type of induction is induction on natural numbers.

- Base case: Show that the property holds for $n = 0$.
- Inductive step: Assuming that the property holds for n , show that the property holds for $n + 1$.

In the inductive step, the assumption is called the **Induction Hypothesis**.

Structural Induction

In functional programming, we can use induction to reason about functions defined over datatypes. For example, given the list datatype:

```
data [a] = [] | a : [a]
```

we obtain the following inductive principle:

- **Base case:** Show that the property holds for $xs = []$.
- **Inductive step:** Assuming that the property holds for xs , show that the property holds for $(x:xs)$.

Structural Induction

- Consider the map function:

$\text{map} :: (a \rightarrow b) \rightarrow [a] \rightarrow [b]$

$\text{map } f [] = []$

$\text{map } f (x:xs) = f x : \text{map } f xs$

$\text{id } x = x$

- It should be clear that mapping the identity function returns the same list back:

$\text{map id } xs \equiv xs$

Can we prove it?

Equational reasoning in mathematics

map id xs

$\equiv \{\text{induction on xs}\}$

1) Base Case: $\text{xs} = []$

map id []

$\equiv \{\text{definition of map}\}$

$[]$

Equational reasoning in mathematics

map id xs

\equiv {induction on xs}

2) Inductive Case: $xs = (y:ys)$

map id (y:ys)

\equiv {definition of map}

id y : map id ys

\equiv {definition of id}

y : map id ys

\equiv {Induction Hypothesis}

y : ys

Equational reasoning in mathematics

- Consider the map function again:

$$\begin{aligned}\text{map} &:: (a \rightarrow b) \rightarrow [a] \rightarrow [b] \\ \text{map } f \ [] &= [] \\ \text{map } f \ (x:xs) &= f \ x : \text{map } f \ xs\end{aligned}$$
$$(f \cdot g) \ x = f \ (g \ x)$$

- Do you think the following is true?

$$\text{map } f \ (\text{map } g \ xs) \equiv \text{map } (f \cdot g) \ xs \quad \text{— map fusion}$$

Can we prove it?

Equational reasoning in mathematics

$\text{map } f (\text{map } g \text{ xs})$

$\equiv \{\text{Induction on xs}\}$

1) Base Case: $\text{xs} = []$

$\text{map } f (\text{map } g [])$

$\equiv \{\text{definition of map}\}$

$\text{map } f []$

$\equiv \{\text{definition of map}\}$

$[]$

$\equiv \{\text{definition of map}\}$

$\text{map } (f . g) []$

Equational reasoning in mathematics

$\text{map } f (\text{map } g \text{ xs})$

$\equiv \{\text{Induction on xs}\}$

2) Inductive Case: $\text{xs} = (y:\text{ys})$

$\text{map } f (\text{map } g (y:\text{ys}))$

$\equiv \{\text{definition of map}\}$

$\text{map } f (g \text{ y} : \text{map } g \text{ ys})$

$\equiv \{\text{definition of map}\}$

$f (g \text{ y}) : \text{map } f (\text{map } g \text{ ys})$

$\equiv \{\text{Induction Hypothesis}\}$

$f (g \text{ y}) : \text{map } (f . g) \text{ ys}$

$\equiv \{\text{definition of } .\}$

$(f . g) \text{ y} : \text{map } (f . g) \text{ ys}$

$\equiv \{\text{definition of map}\}$

$\text{map } (f . g) (y:\text{ys})$

Functors

It turns out that the map function, together with the laws:

$\text{map } f (\text{map } g \text{ xs}) \equiv \text{map } (f . g) \text{ xs}$ — map fusion
 $\text{map id xs} \equiv \text{xs}$ — map identity

Can be generalized:

class Functor f where

$\text{fmap} :: (a \rightarrow b) \rightarrow f a \rightarrow f b$

— Laws

— $\text{fmap } f (\text{fmap } g \text{ fa}) \equiv \text{fmap } (f . g) \text{ fa}$

— $\text{fmap id fa} \equiv \text{fa}$

List Functor

Given the map function and our two proofs, it is easy to create an instance for Functor:

```
instance Functor [] where  
    fmap = map
```

Other Functors

Functors are quite common, nearly all parametrised types (Example: `[a]`, `Maybe a`, `IO a`, ...) are functors

— `data Maybe a = Nothing | Just a`

`instance Functor Maybe where`

`-- fmap :: (a -> b) -> Maybe a -> Maybe b`

`fmap f Nothing = Nothing`

`fmap f (Just x) = Just (f x)`

Maybe Functor

fmap id ma

\equiv {case analysis on ma}

1) Case ma = Nothing

fmap id Nothing

\equiv {definition of fmap}

Nothing

2) Case ma = Just x

fmap id (Just x)

\equiv {definition of fmap}

Just (id x)

\equiv {definition of id}

Just x

Maybe Functor

`fmap f (fmap g fa)`

\equiv {case analysis on fa}

1) Case `fa = Nothing`

`fmap f (fmap g Nothing)`

\equiv {definition of fmap}

`fmap f Nothing`

\equiv {definition of fmap}

`Nothing`

\equiv {definition of fmap}

`fmap (f . g) Nothing`

Exercises:

1) Consider the definitions:

$$\begin{aligned}\text{map} &:: (a \rightarrow b) \rightarrow [a] \rightarrow [b] \\ \text{map } f [] &= [] \\ \text{map } f (x:xs) &= f\ x : \text{map } f\ xs\end{aligned}$$
$$\begin{aligned}\text{length} &:: [a] \rightarrow \text{Int} \\ \text{length } [] &= 0 \\ \text{length } (x:xs) &= 1 + \text{length } xs\end{aligned}$$

Prove that:

$$\text{length } (\text{map } f\ xs) \equiv \text{length } xs$$

$\text{length } (\text{map } f \text{ } xs)$

$\equiv \{ \text{Induction on } xs \}$

1) Base case: $xs = []$

$\text{length } (\text{map } f [])$

$\equiv \{ \text{definition of map} \}$

$\text{length } []$

2) Inductive case: $xs = (y:ys)$

$\text{length } (\text{map } f (y:ys))$

$\equiv \{ \text{definition of map} \}$

$\text{length } (f \ y : \text{map } f \ ys)$

$\equiv \{ \text{definition of length} \}$

$1 + \text{length } (\text{map } f \ ys)$

$\equiv \{ \text{Induction Hypothesis} \}$

$1 + \text{length } ys$

$\equiv \{ \text{definition of length} \}$

$\text{length } (y:ys)$

Exercises:

2) Consider the definitions:

$$\begin{aligned}\text{map} &:: (a \rightarrow b) \rightarrow [a] \rightarrow [b] \\ \text{map } f [] &= [] \\ \text{map } f (x:xs) &= f x : \text{map } f xs\end{aligned}$$
$$\begin{aligned}(++) &:: [a] \rightarrow [a] \rightarrow [a] \\ [] ++ ys &= ys \\ (x:xs) ++ ys &= x : (xs ++ ys)\end{aligned}$$

Prove that:

$$\text{map } f (xs ++ ys) \equiv \text{map } f xs ++ \text{map } f ys$$

$\text{map } f \text{ (xs ++ ys)}$

$\equiv \{\text{Induction on xs}\}$

1) Case $\text{xs} = []$

$\text{map } f \text{ ([] ++ ys)}$

$\equiv \{\text{definition of ++}\}$

$\text{map } f \text{ ys}$

$\equiv \{\text{definition of ++}\}$

$[] ++ \text{map } f \text{ ys}$

$\equiv \{\text{definition of map}\}$

$\text{map } f \text{ [] ++ map } f \text{ ys}$

Exercises:

3) Consider the definitions:

```
data Tree a = Leaf | Fork a (Tree a) (Tree a)
```

```
mapT :: (a -> b) -> Tree a -> Tree b
```

```
mapT f Leaf      = Leaf
```

```
mapT f (Fork x l r) = Fork (f x) (mapT f l) (mapT f r)
```

```
flatten :: Tree a -> [a]
```

```
flatten Leaf      = []
```

```
flatten (Fork x l r) = x : flatten l ++ flatten r
```

Exercises:

3) Prove that:

$$\text{mapT id} \equiv \text{id}$$

$$\text{mapT f (mapT g xs)} \equiv \text{mapT (f . g) xs}$$

$$\text{flatten . mapT f} \equiv \text{map f . flatten}$$
